PREFACE

The study reported herein was authorized as a part of the Civil Works Research and Development Program by the Office, Chief of Engineers (OCE), US Army. This particular work unit, Erosion Control of Scour During Construction, is part of the Improvement of Operations and Maintenance Techniques (IOMT) Program. Mr. James L. Gottesman was the OCE Technical Monitor for the IOMT Program during preparation and publication of this report.

This study was conducted during the period 1 January 1981 through 31 March 1982 by personnel of the Hydraulics Laboratory of the US Army Engineer Waterways Experiment Station (WES) under the general supervision of Messrs. H. B. Simmons, Chief of the Hydraulics Laboratory; F. A. Herrmann, Jr., Assistant Chief of the Hydraulics Laboratory; R. A. Sager, Chief of the Estuaries Division and IOMT Program Manager; Dr. R. W. Whalin and Mr. C. E. Chatham, former and acting Chiefs of the Wave Dynamics Division, respectively; Mr. D. D. Davidson, Chief of the Wave Research Branch; and Dr. J. R. Houston, Research Hydraulic Engineer and Principal Investigator for the Erosion Control of Scour During Construction work unit. The Wave Dynamics Division was transferred to the Coastal Engineering Research Center (CERC) of the WES on 1 July 1983 under the direction of Dr. Whalin, Chief of the Coastal Engineering Research Center. Computer programming for this study was performed by Ms. L. Chou, Mathematician. This report was prepared by Dr. Houston and Ms. Chou.

Commanders and Directors of WES during the conduct of this investigation and the preparation and publication of this report were COL Nelson P. Conover, CE, and COL Tilford C. Creel, CE. Technical Director was Mr. F. R. Brown.

# EROSION CONTROL OF SCOUR DURING CONSTRUCTION

## FINITE--A NUMERICAL MODEL FOR COMBINED REFRACTION AND DIFFRACTION OF WAVES

### PART I: INTRODUCTION

#### Statement of the Problem

1. It is frequently necessary to construct large engineering works of improvement in the surf and nearshore zone to protect harbor entrances, recreational beaches, and navigation channels. These structures, usually built from quarried rock or precast concrete, are placed in position by crane or barge. When these major structures are erected in the coastal zone they alter the existing currents. Shallow-water surface gravity waves breaking on the new structure will cause bottom material to be suspended and transported from the region by longshore or other currents that may exist. <sup>Since</sup> This removal of material is often not compensated by an influx of additional material, and the result is a scour hole, or erosion, that usually develops along the toe of the structure.

2. In order to ensure structural stability and functional adequacy of the works of improvement, any scour area must be filled with nonerodible material (sufficiently stable to withstand the environmental forces to which it will be subjected). This may result in additional quantities of material being required during construction that can potentially lead to substantial cost overruns. To minimize potential cost increases due to scour during construction, it is necessary to quantify the probability and ultimate extent of potential scour during the scheduled construction period. This is an extremely complex problem and quantification of the probability of potential scour will likely be site-specific.

3. Since waves and wave-induced currents play an important role in producing scour near structures, it is important to predict the wave field in the vicinity of structures. Structures of interest may have complex shapes and the surrounding bathymetry may be very complex. Both long- and short-period waves may attack the structure from many different angles.

### Purpose of the Study

4. The purpose of this study is to develop a numerical model that can determine wave fields near arbitrary structures in a region of arbitrary and variable bathymetry. The model must be capable of simulating both long and short waves approaching structures from any arbitrary direction. In addition, the model must be sufficiently efficient to allow application to real coastal engineering problems.

Background

5. Short waves have wavelengths that are sufficiently short (wavelength to depth ratio less than approximately 20) that propagation speeds are a function of wave frequency. In the nearshore region, short waves with periods from a few seconds to approximately 20 sec play an important role in the movement of sediment and the stability of coastal structures.

6. Equations that govern long-wave propagation over variable depths have been known for some time (Lamb 1932). However, for shorter period waves where frequency dispersion is important, the theory has included only constant depths. Attempts have been made (Pierson 1951; Eckart 1952) to develop a two-dimensional equation for combined refraction and diffraction that would govern short-wave propagation in a region of variable depth; however, the equations developed do not reduce to the appropriate simple refraction equation after neglecting the curvature of the amplitude function and they also do not reduce to the linear long-wave equation in the case of small water depth. In recent years, Boussinesq-type equations also have been used to study the propagation of short-period waves. These equations include terms that govern both frequency dispersion and nonlinearity. Two-dimensional modeling of these equations is difficult since the frequency dispersion term is third order, therefore requiring a third-order accurate numerical scheme. Abbott, Petersen, and Skovgaard (1978) have presented a time-marching, two-dimensional, finite difference numerical model with a third-order accurate implicit solution scheme. However, a time-marching scheme requires significant computational time. In addition, the finite difference method does not realistically model a complex land-water interface as a result of the stair-step representation and has difficulties in allowing scattered waves to propagate out of a finite extent grid, since these scattered waves are not known a priori.

7. Berkhoff (1972) and Schonfeld (1972) have derived a two-dimensional wave equation that governs short-wave propagation over moderately varying depths. Smith and Sprinks (1975) gave a formal derivation of this equation. In the present study, a hybrid finite element model (FINITE) is used to solve this wave equation. The method combines a finite element solution over a finite extent region of variable depth with an analytical solution for a

surrounding infinite region of constant depth.

### Wave Equation

9. The propagation of periodic, small amplitude, surface gravity waves over a variable depth seabed of mild slope is governed by the following equation.

$$\nabla \cdot (c c_g \nabla \phi) + \frac{c}{c} g \omega^2 \phi = 0 \quad (1)$$

where

$\nabla$  = horizontal gradient operator, dimensionless

$c$  = phase velocity, ft/sec\* =  $(g/k \tanh kh)^{1/2}$

$g$  = gravitational constant, 32.174 ft/sec<sup>2</sup>

$k$  = wave number,  $2\pi/L$ , 1/ft

$h$  = still-water depth, ft

$c_g$  = group velocity, ft/sec =  $1/2 c(1 + G)$

$G$  =  $2k h/\sinh 2kh$ , ft/sec

$\phi$  = velocity potential defined by  $\bar{u} = \nabla \phi$ , ft<sup>2</sup>/sec

$\bar{u}$  = two-dimensional velocity vector, ft/sec

$\omega$  = angular frequency,  $2\pi/T$ , 1/sec

10. Equation 1 was derived by Berkhoff (1972) and Schonfeld (1972) and is discussed in detail by Jonsson and Brink-Kjaer (1973). This equation governs both refraction and diffraction. It reduces to the well-known "eikonal" equation governing refraction by neglect of the variation of the amplitude function in the horizontal plane. The equation reduces to the diffraction Helmholtz equation in deep or constant-depth water and to the linear long-wave equation in shallow water.

11. Finite element numerical models have been used to solve Equation 1. Berkhoff (1972, 1976) linked a finite element solution of Equation 1 over a variable depth region to a source distribution for a constant-depth outer region. However, as noted by Chen and Mei (1974), Berkhoff (1972) did not use a proper functional with the consequence that his global stiffness matrix was nonsymmetric and thus inconvenient numerically for all but the simplest problems. Bettess and Zienkiewicz (1977) also developed a finite element solution

---

\* A table of factors for converting US customary units of measurements to metric (SI) units is presented on page 3.

of Equation 1. However, they used infinite elements to cover the constant-depth outer region. The shape function used in the infinite elements had an exponentially decreasing term in the direction away from the inner region. The choice of a decay length was somewhat arbitrary; but the solutions were not, in general, too sensitive to the exact value. A disadvantage of this technique is that the infinite elements increase the number of equations to be solved. If a problem requires a large number of elements because the region of interest is large and the incident wavelengths are short, this solution can require substantial computational time.

12. Equation 1 also has been solved by a parabolic approximation (Radder 1979). The approximation is derived from splitting the wave field into transmitted and reflected components and then neglecting the reflected components. This approach is applicable to some propagation problems but is not appropriate for problems involving wave interaction with coastal structures such as breakwaters.

#### Finite Element Solution

13. Equation 1 is solved by program FINITE using a hybrid finite element method originally developed by Chen and Mei (1974) to solve the diffraction Helmholtz equation in a constant-depth region. Space is divided into two regions as shown in Figure 1 (finite inner region A and infinite outer region B). Conventional finite elements are used in the variable depth region A. A single superelement is used to cover the constant-depth infinite region B. Variational principles are used that incorporate the matching conditions between the regular elements and the superelement as natural conditions. Thus a symmetric global stiffness matrix is obtained that is very advantageous for highly complex problems.

14. The variational principle for the boundary value problem requires that the following functional be stationary with respect to arbitrary first variation of the velocity potential  $\phi$  :

$$\begin{aligned}
 F(\phi) = & \iint_A \frac{1}{2} \left[ \frac{cc}{g} (\nabla\phi)^2 - \frac{\omega^2 c}{gc} \phi^2 \right] dA \\
 & + \int_{\partial B_\infty} \frac{ikcc}{2g} (\phi - \phi_I)^2 dL - \int_{\partial B_\infty} \frac{cc}{g} \frac{\partial\phi_I}{\partial n} \phi dL \quad (2)
 \end{aligned}$$

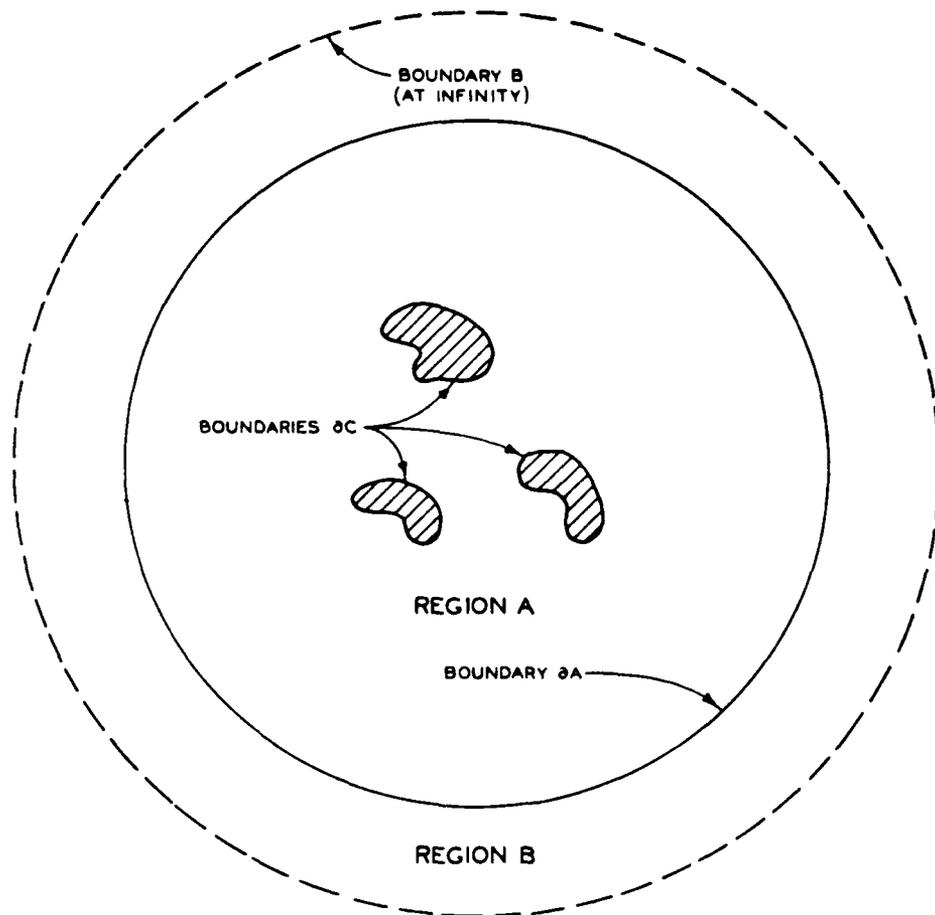

Figure 1. Regions of computation

where  $\phi_I$  and  $\phi_R$  are the incident and reflected wave velocity potentials, respectively;  $n$  is a unit normal; and the last two integrals are line integrals at infinity. Analogous to the derivation of Chen and Mei (1974), this functional can be rewritten as follows:

$$\begin{aligned}
 F(\phi) = & \iint_A \frac{1}{2} \left[ \frac{cc}{g} (\nabla\phi_A)^2 - \frac{\omega^2 c}{gc} \phi_A^2 \right] dA + \int_{\partial A} \frac{1}{2} \frac{cc}{g} (\phi_B - \phi_I) \frac{\partial(\phi_B - \phi_I)}{\partial n_A} \\
 & - \int_{\partial A} \frac{cc}{g} \phi_A \frac{\partial(\phi_R - \phi_I)}{\partial n_A} - \int_{\partial A} \frac{cc}{g} \phi_A \left| \frac{\partial\phi_I}{\partial n_A} \right. \\
 & \left. + \int_{\partial A} \frac{cc}{g} \phi_I \frac{\partial(\phi_B - \phi_I)}{\partial n_A} + \int_{\partial A} \frac{cc}{g} \phi_I \frac{\partial\phi_I}{\partial n_A} \right. \quad (3)
 \end{aligned}$$

where  $\phi_B$  and  $\phi_A$  are the velocity potentials in regions B and A, respectively, and  $n_A$  is a unit normal to the boundary separating regions B and A.

15. Note that all integrals are evaluated within region A or along  $\partial A$ . Thus the variational principle is a localized one. As discussed by Aranha, Mei, and Yue (1979), this variational principle can be replaced by an equivalent weak formulation.

16. The inner region A is assumed to have a variable depth and to be of finite extent. This region is subdivided into finite elements. Here the elements are triangular with simple linear shape functions. The infinite region B (or semi-infinite if a harbor located along an infinite coastline is of concern) is assumed to have a constant depth and is covered with a single superelement. Since region B has a constant depth, the governing equation is the diffraction Helmholtz equation. An analytical solution for the velocity potential in region B is well known and can be expressed as follows:

$$\phi_B = \sum_{n=0}^{\infty} H_n(kr)(\alpha_n \cos n\theta + \beta_n \sin n\theta) \quad (4)$$

where  $\alpha_n$  and  $\beta_n$  are constant and unknown coefficients,  $H_n(kr)$  is Hankel function of the first kind, and  $r$  and  $\theta$  are radial and angular variables in polar coordinates. For a semi-infinite region B and a straight infinite coastline,  $\phi_B$  can be expressed as follows:

$$\phi_B = \sum_{n=0}^{\infty} \alpha_n H_n(kr) \cos n\theta \quad (5)$$

The velocity potentials given in Equations 4 and 5 satisfy the Sommerfeld radiation condition that the scattered waves must behave as outgoing waves at infinity. Thus region B can be considered to be a single superelement with shape function given by Equations 4 and 5.

17. If the shape functions are used to evaluate the integrals of Equation 3 and the functional is extremized with respect to the unknowns, a set of linear algebraic equations is obtained. Of course, the infinite series given by Equations 4 and 5 must be truncated at some finite extent. The number of terms that must be retained depends upon the incident wavelength and may be found by increasing the number of terms until the solution is insensitive to

the addition of further terms. Solution of the boundary value problem thus reduces to the solution of  $N$  linear algebraic equations for  $N$  unknowns (where  $N$  is the number of node points in the finite element discretization plus the number of unknowns in the truncated series). That is,

$$\begin{matrix} [K] & \{\psi\} & = & \{Q\} \\ N \times N & N \times 1 & & N \times 1 \end{matrix} \quad (6)$$

The symmetric complex coefficient matrix  $[K]$  is in general large, sparse, and banded. It can be stored and manipulated in the computer in a packed form (Chen and Mei 1974). The packed form is chosen to be a rectangular array ( $N$  variables in length and the semibandwidth in width). Only elements of  $[K]$  on and above the diagonal and within the band width need to be stored in the packed form.

18. Although the packed form of  $[K]$  greatly reduces the required computer memory, the problems discussed later are so large that even memory requirements of the packed form of  $[K]$  are excessive. However, since the symmetric coefficient matrix is positive definite, a solution is possible by elimination methods without pivoting. Without pivoting, elimination performed using one row affects only the triangle of elements within the band below that row. Thus the packed form of  $[K]$  can be partitioned into several smaller blocks. Using Gaussian elimination, only two blocks at a time are involved in the reduction and back substitution with the remainder of the blocks kept in peripheral storage. This technique allows the solution of extremely large matrices.

#### Verification

19. To verify this numerical model, comparisons were made between the finite element calculations and both an analytical and a numerical solution for the interaction of waves with a circular island on a paraboloidal shoal. Figure 2 is a sketch of the problem. Hom-ma (1950) presented the analytical solution to the long-wave equation for plane waves incident upon this island.

20. Many investigators, including Berkhoff (1972, 1976) and Bettess and Zienkiewicz (1977), have compared their finite element solutions of the long-wave equation with Hom-ma's solution. For example, Berkhoff (1972, 1976) used 156 elements to cover the paraboloidal shoal (actually one-half of the

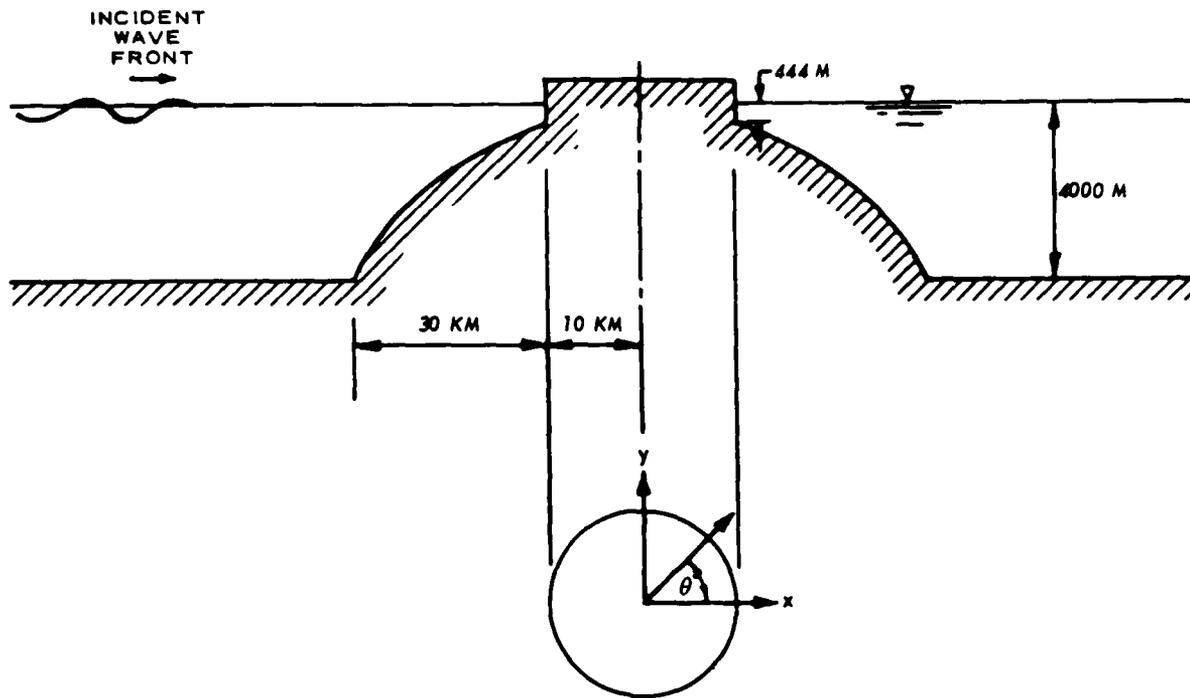

Figure 2. Circular island on a paraboloidal shoal

shoal since by symmetry the solution required calculations for just one-half of the shoal). This number of elements was not sufficient to adequately resolve features of the problem; consequently, Berkhoff's finite element solution differed from Homma's analytical solution by as much as 70 percent at one location. Since Berkhoff did not attempt to use a finer grid, it is likely that his coarse grid required a moderate computational time. The model described in this paper would require less than 0.1 sec of computational time on a CRAY-1 computer to solve Equation 6 using Berkhoff's grid. Bettess and Zienkiewicz (1977) also used a fairly coarse grid similar to Berkhoff's grid.

21. Lautenbacher (1970) used an integral equation solution to solve the long-wave equation for waves interacting with a circular island on a shoal with linear side slopes. He used a coarse circular mesh grid with only 130 points. Because the resulting coefficient matrix was full, the computational time required for a solution was 60 min on an IBM 7094 computer.

22. Figure 3 shows a finite element grid with 2,640 elements used by the model described in this report to solve the problem of the interaction of long waves with a circular island on a paraboloidal shoal (by symmetry only

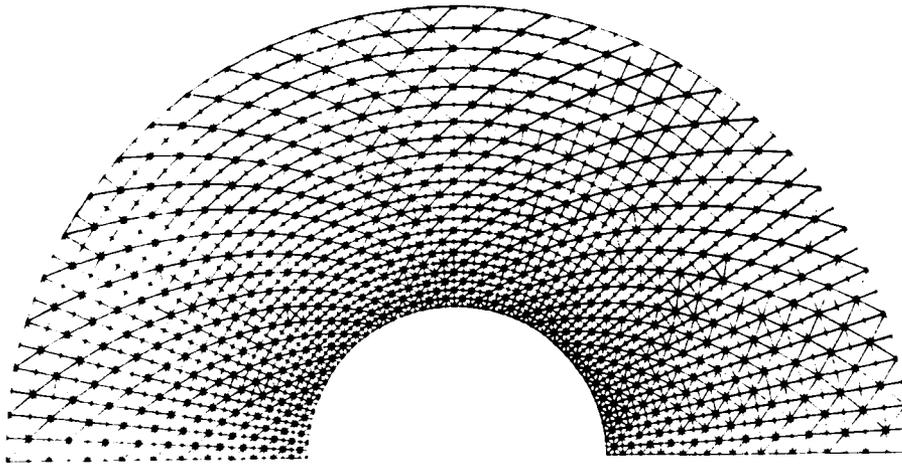

Figure 3. Finite element grid for paraboloidal island (2,640 elements)

half the shoal needs to be considered). Figure 4 shows comparisons between Hom-ma's analytical solution and the finite element model solution for incident waves with five different periods. The agreement is excellent with only slight differences for the 240-sec waves (resulting from lower resolution of the incident wave for shorter period waves). The computational time for solution is approximately 4 sec on a CRAY-1 computer.

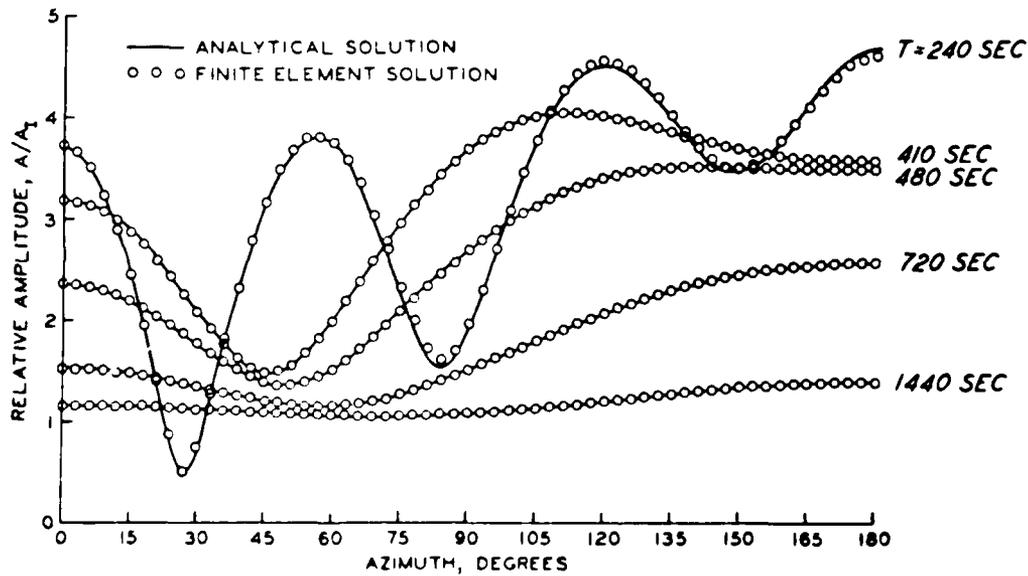

Figure 4. Solutions without dispersion (2,640 element grid)

23. Jonsson, Skovgaard, and Brink-Kjaer (1976) show that for a wave with a 240-sec period interacting with the circular island on a paraboloidal shoal the effect of frequency dispersion is not particularly significant. The ratio of wavelength to water depth for this case is approximately 11. However, for a 120-sec incident wave (wavelength to water depth ratio of less than 5), frequency dispersion is quite significant. In order to maintain a resolution of a 120-sec wave that is approximately equal to that obtained for the 240-sec wave using the 2,640-element grid, it is necessary to reduce element side lengths by a factor of approximately 2. This reduction results in a quadrupling of the number of elements. Figure 5 shows a finite element grid with 10,560 elements used to calculate the interaction of a 120-sec wave with the island.

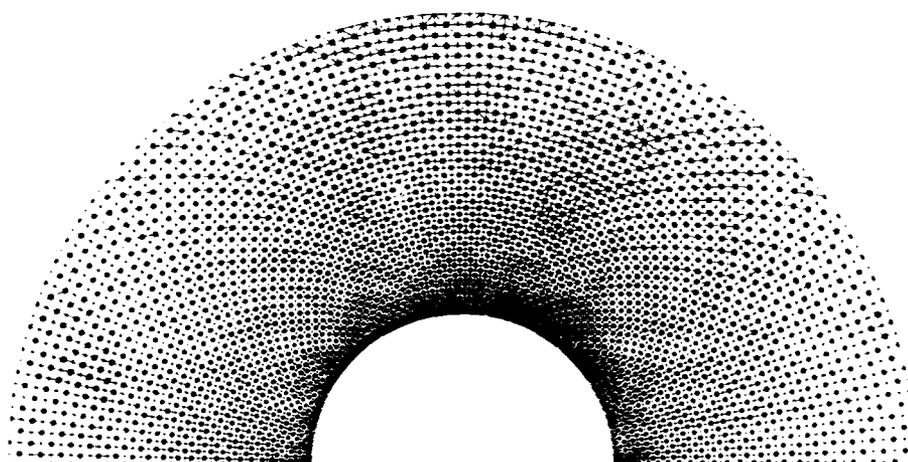

Figure 5. Finite element grid for paraboloidal island (10,560 elements)

24. Figure 6 shows a comparison between the analytical solution of the long-wave equation by Hom-ma (1950) and the finite element solution (grid of Figure 5) for a 120-sec incident wave. Figure 7 also shows a comparison between a numerical solution of Equation 1 using an orthogonal collocation solution and the finite element model solution of this report. In both cases there is excellent agreement. The effect of frequency dispersion is quite significant as shown in Figure 8, where the solutions of the long-wave equation and Equation 1 are overlapped. In fact, the inclusion of frequency dispersion is much more significant a factor than is resolution of the wave form for this particular case. For example, Figure 9 shows a solution including dispersion using the 2,640-element grid. The agreement between the finite element and

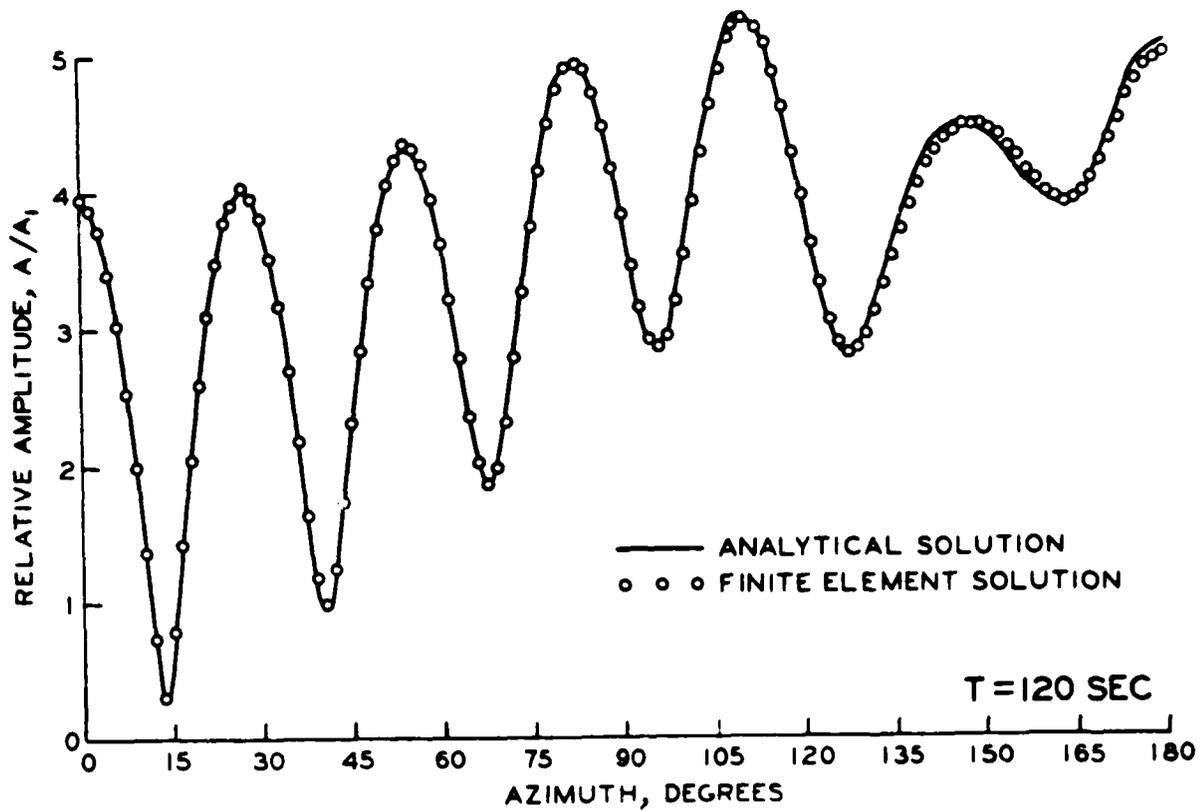

Figure 6. Solutions without dispersion (10,560-element grid)

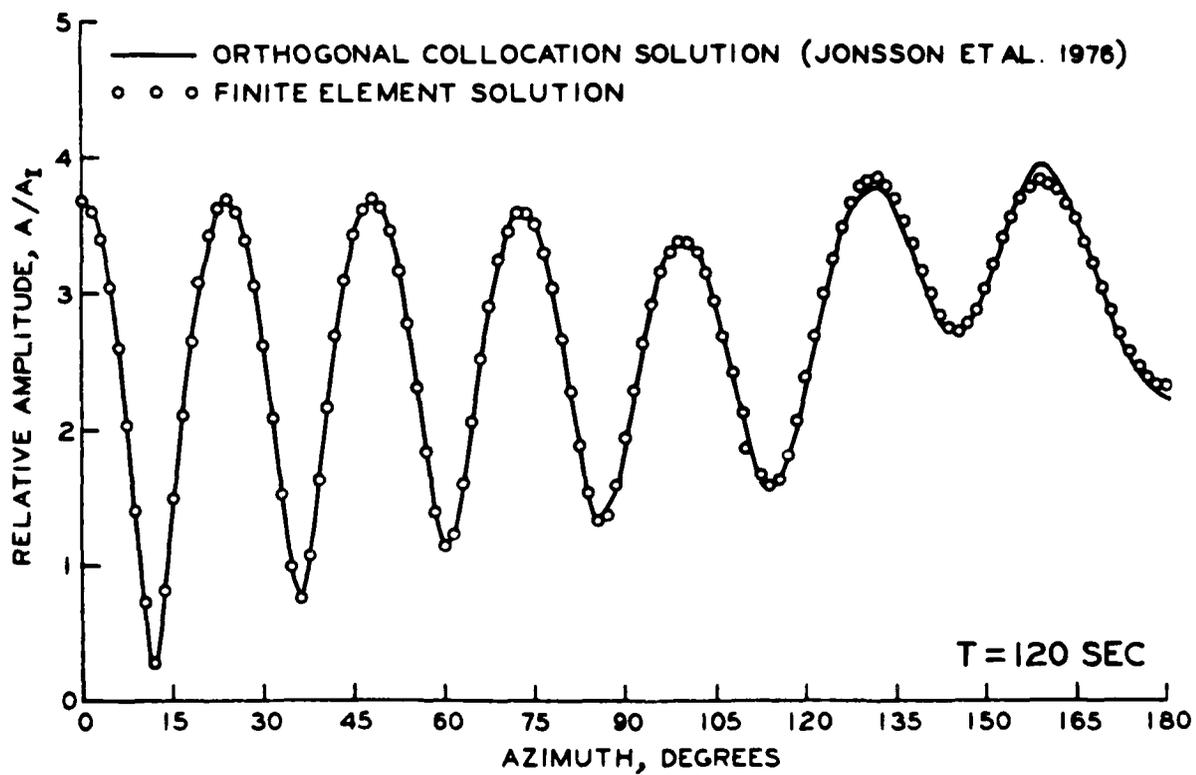

Figure 7. Solutions with dispersion (10,560-element grid)

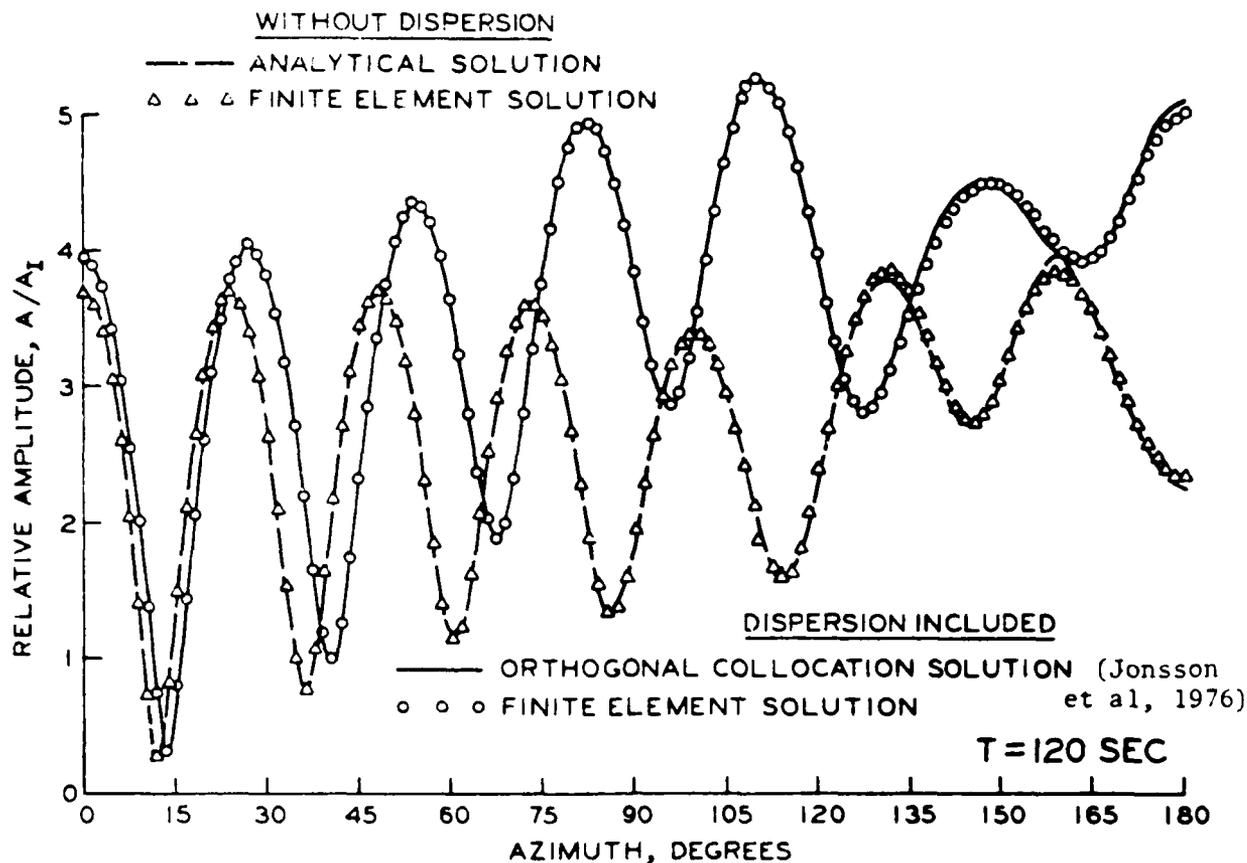

Figure 8. Effect of dispersion

collocation solutions is much better using the 2,640-element grid and including dispersion than is obtained using the 10,560-element grid without dispersion.

25. The computational time requirement to solve a problem using the 10,560-element grid is less than 1 min on a CRAY-1. This is extremely modest considering the very large size of this finite element grid. The computational time of the model is proportional to the number of nodes times the bandwidth of the coefficient matrix squared. This grid has more than 50 times the number of nodes contained in the grid used by Berkhoff (1972, 1976) and a bandwidth approximately 3.3 times greater. Thus the computational time requirement is almost 600 times greater for this grid than for Berkhoff's grid. The computer memory requirements also are very modest as a result of the partitioning of the coefficient matrix. Although the packed form of the coefficient matrix had approximately 1.7 million terms for this problem, only 45,000 terms were in central memory at any given time with the remainder in peripheral storage.

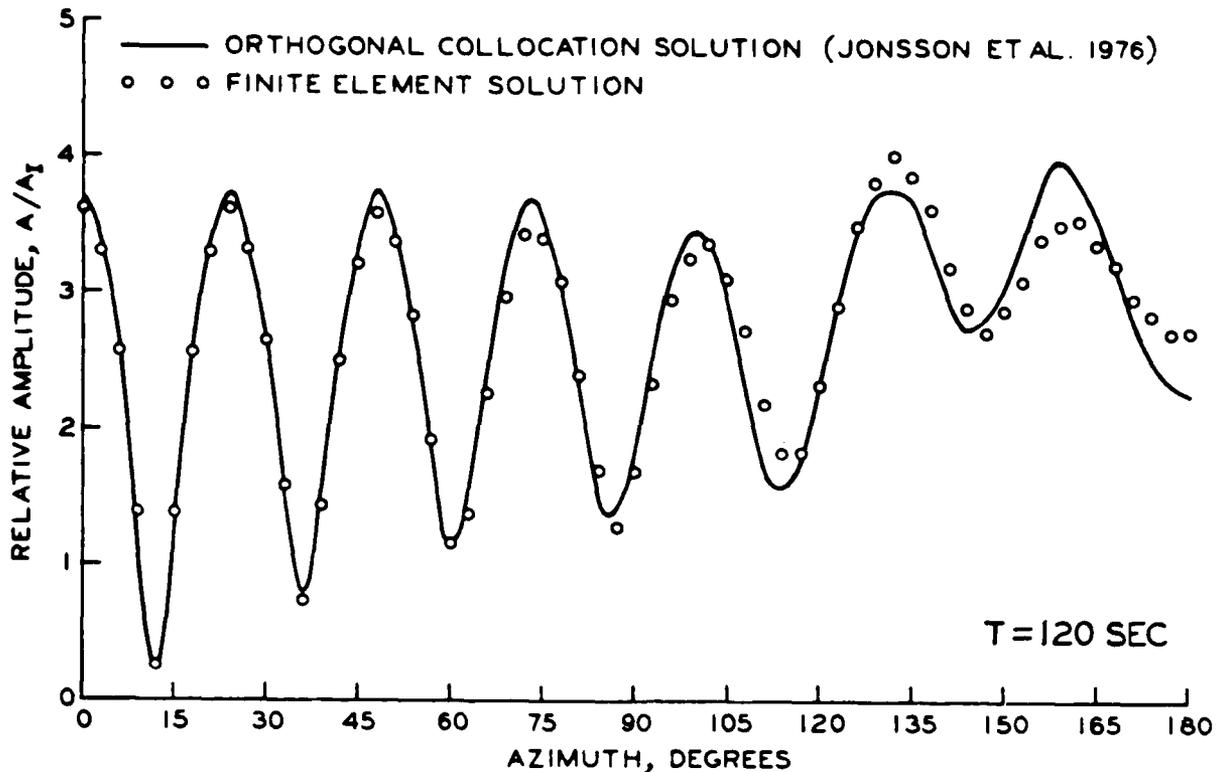

Figure 9. Solutions with dispersion (2,640-element grid)

Comparison with Three-Dimensional Numerical Model

26. Equation 1 was derived assuming that the bathymetry was slowly varying. This mild slope approximation is valid for the slow bathymetric variations of the paraboloidal shoal shown in Figure 2. However, the approximation is not appropriate for many practical problems involving the interaction of waves with *man-made* structures. For these problems, it is necessary to use a fully three-dimensional model such as the hybrid three-dimensional finite element developed by Yue, Chen, and Mei (1976). Of course, a three-dimensional model requires substantial computational time. Therefore it is of interest to consider how well a two-dimensional mild-slope model compares with a three-dimensional model for a problem where the mild-slope approximation is strongly violated.

27. Yue, Chen, and Mei (1976) used a three-dimensional model to consider the interaction of small amplitude plane waves with an elliptic island on a circular base. Figure 10 illustrates the problem and shows the finite

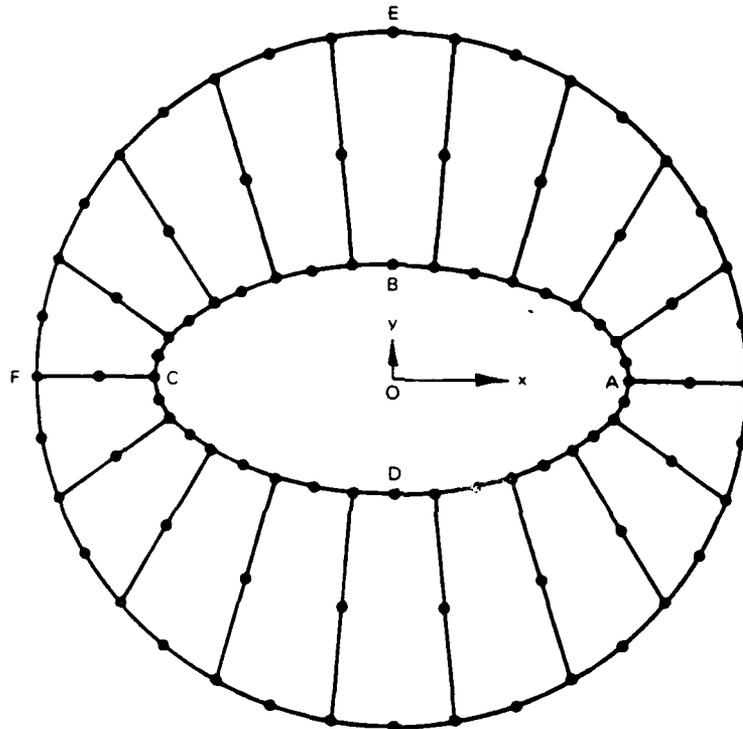

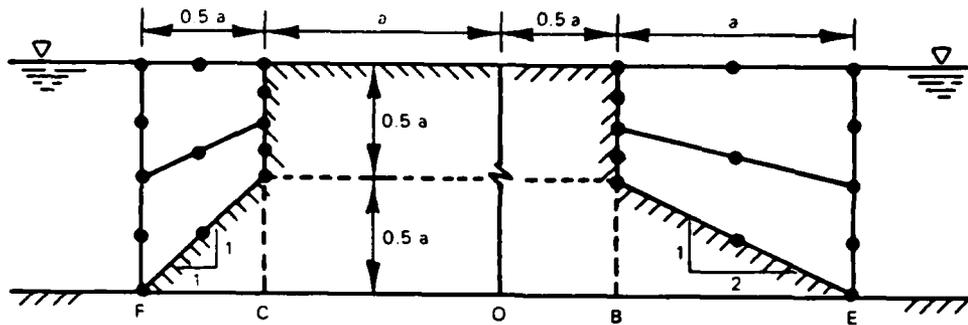

Figure 10. Elliptic island and three-dimensional grid

element grid used by Yue, Chen, and Mei (1976). Bottom side slopes vary from 1V on 1H to 1V on 2H and violate the mild-slope assumption.

28. Figure 11 shows the two-dimensional finite element grid used by the model described in this report to simulate the interaction of small amplitude plane waves with the elliptical island. Figures 12 and 13 show the interaction of waves ( $k_0 a = 1$  and two incident directions) with the elliptical island. The amplification factors and phases around the elliptical island calculated by the three-dimensional model of Yue, Chen, and Mei (1976) and the

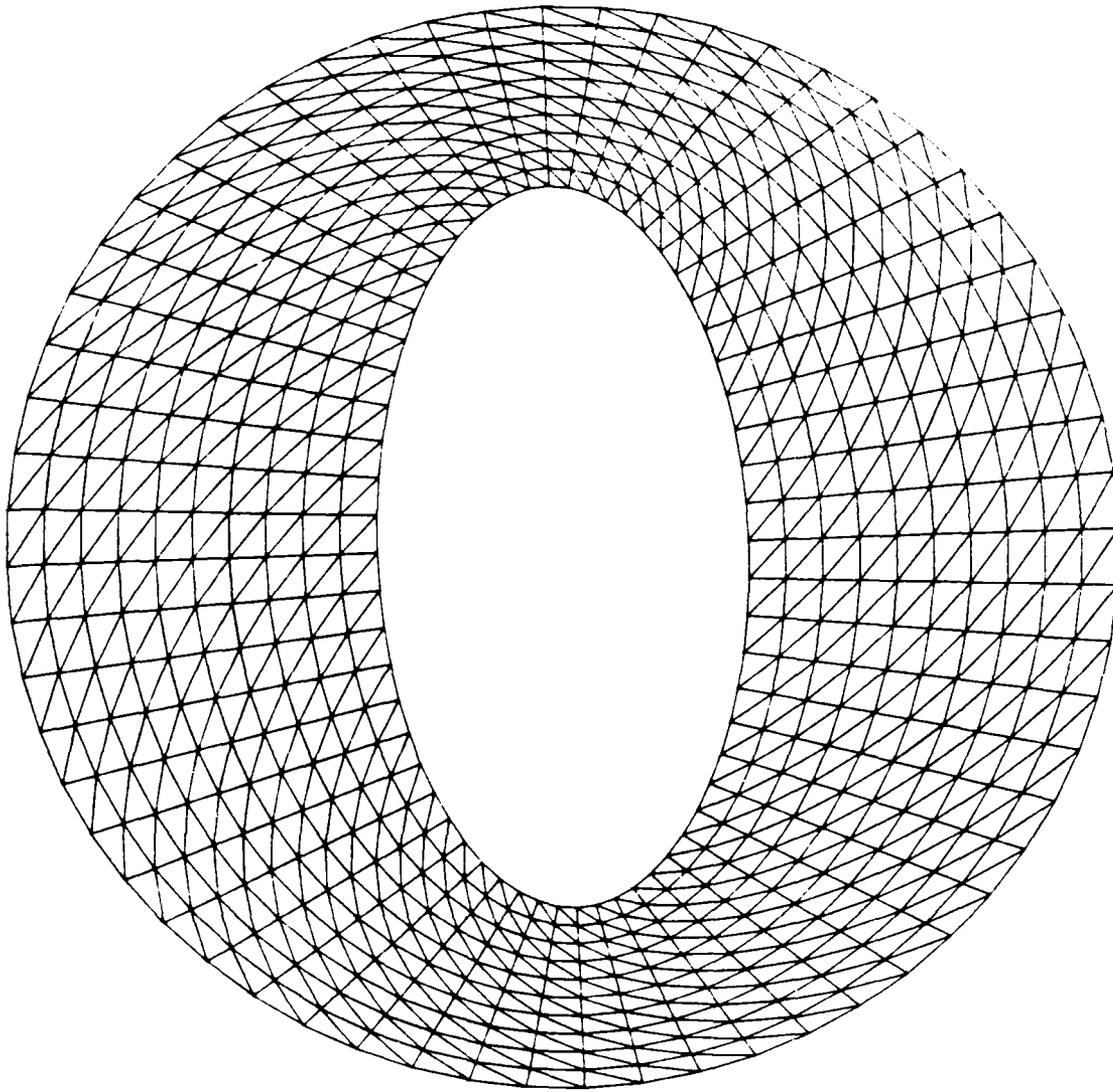

Figure 11. Finite element grid for elliptical island

two-dimensional model described in this report are shown. The maximum difference in amplification factors is not much greater than 10 percent. Similar agreement was found for greater values of  $k_0 a$ .

29. Although the two-dimensional model cannot perfectly reproduce the three-dimensional model results, the difference may be within the accuracy requirements of many engineering applications. Of course, the computational requirements of the two-dimensional model are very modest compared with the requirements of the three-dimensional model. For the problem of waves interacting with the elliptical island, the three-dimensional model required 2.6 min of computational time on an IBM 370/168 computer for each wave period. The

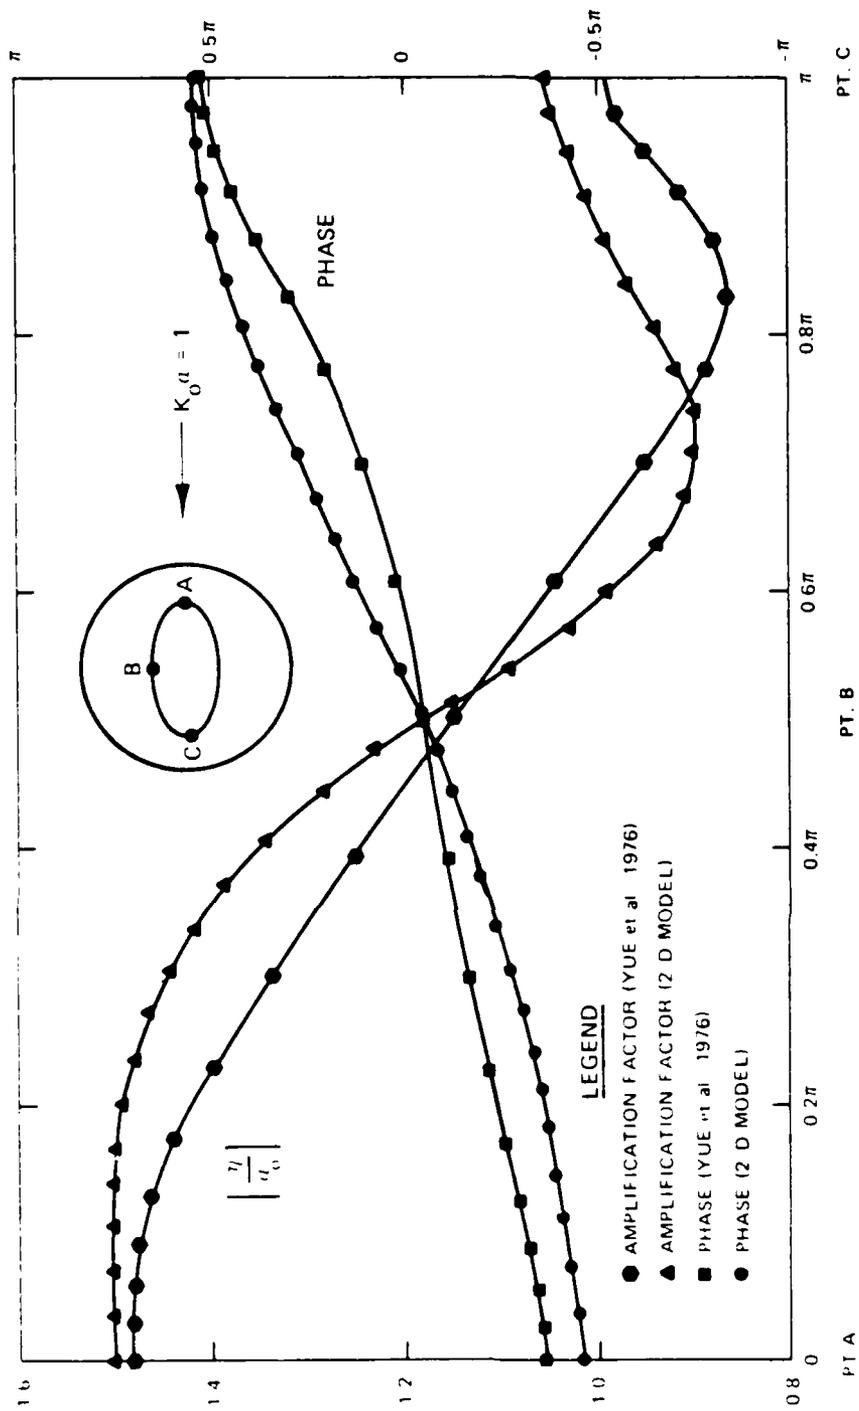

Figure 12. Comparison of model results (incident azimuth 0)

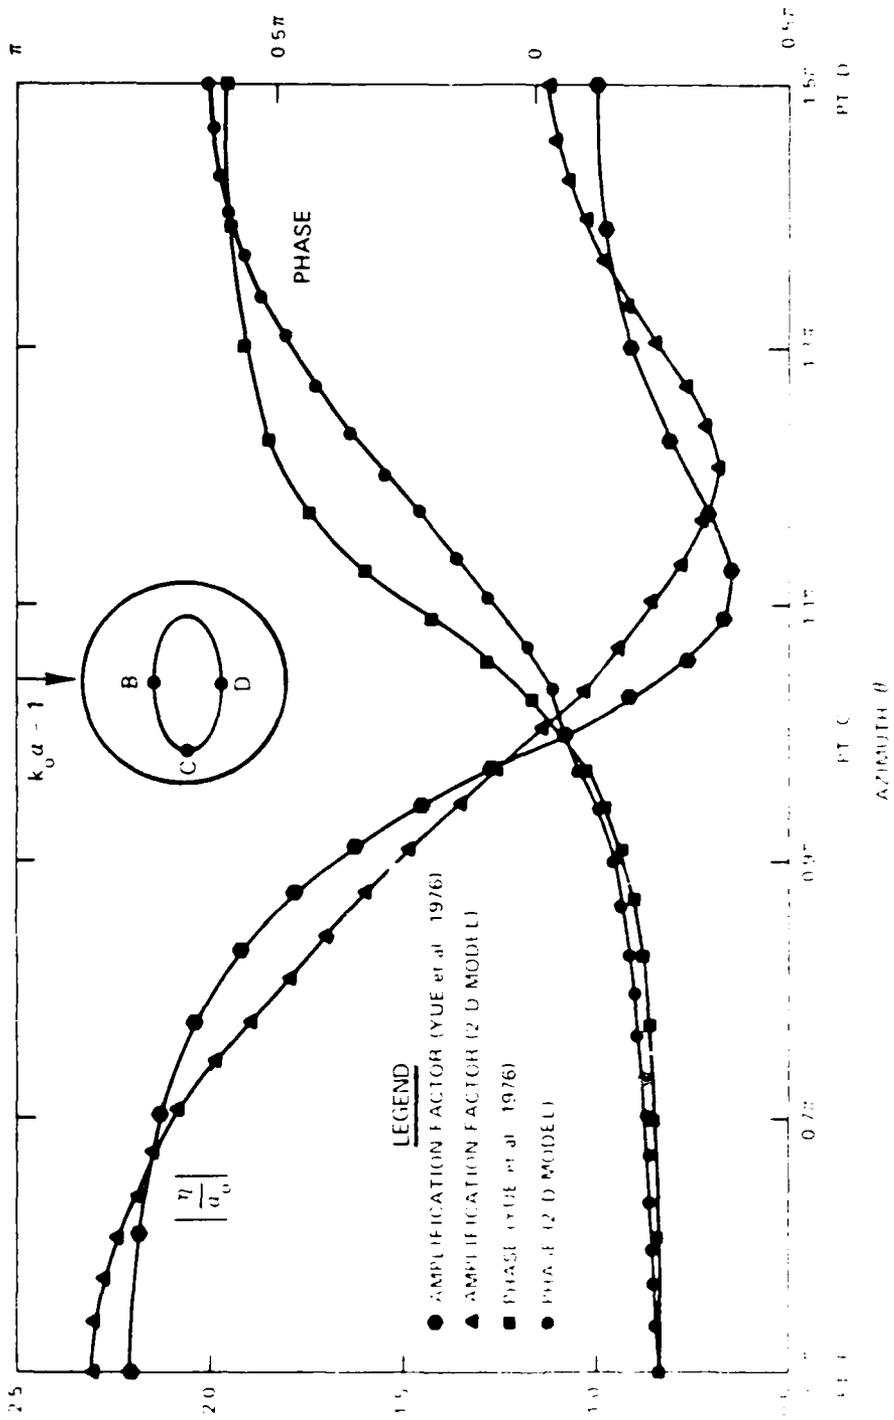

Figure 13. Comparison of model results (measured at azimuth 90°)

two-dimensional model required less than 2 sec of computational time on a CRAY-1 computer. Part of the difference in computational time is a consequence of the unknown relative speeds of the two computers.

30. The difference in computational time of the two- and three-dimensional models becomes more significant for larger problems. For example, Yue, Chen, and Mei (1976) estimate that approximately 6 hr of computational time on an IBM 370/168 computer would be necessary to calculate the interaction of a wave with a period of 8.5 sec or greater with a particular offshore harbor. If a resolution of 10 grid points per wavelength is maintained, the two-dimensional model would require an estimated computational time of only 0.5 to 1 min to perform the same calculation on a CRAY-1 computer.

#### Comparison with Laboratory Experiments

31. Putnam and Arthur (1948) performed the pioneering laboratory experiments that considered diffracted waves in the lee of an impermeable breakwater located in constant-depth water. Mobarek (1962) performed similar experiments except that a linear bottom slope was used in the lee of the breakwater and a very small model (72 ft<sup>2</sup>) was used. In order to study the phenomenon of combined refraction and diffraction near structures, laboratory experiments were performed by Hales (1980). In these experiments an impermeable breakwater was located perpendicular to a straight coastline. A linear bottom slope extended from some distance in front of the breakwater to the shoreline.

32. The laboratory facility used in these tests covered an area of approximately 2,500 ft<sup>2</sup>. The breakwater was 15 ft long and 1 in. thick. The water depth in the facility decreased from 1.0 ft to 0.0 ft over a distance of 20 ft. The sidewalls that laterally bounded the facility were curved to follow wave orthogonals. A plunger-type wave maker was used to generate small amplitude sinusoidal waves that approached the breakwater at an angle. An array of 32 parallel-wire, resistance-type sensors was used to measure the waves. The gages were supported by a large stand so that only the measuring wires of the gages were in the water (i.e., the gages did not require individual feet for support). Information was recorded and analyzed by a minicomputer.

33. One problem in simulating these laboratory tests numerically is that the waves break in the hydraulic model near the shoreline and thus dissipate

their energy. There is no mechanism to dissipate energy in the numerical model described in this paper. However, dissipation can be simulated by allowing waves to continue to propagate out of the problem area. Figure 14 illustrates schematically how this is done. The breakwater and the linear slope are numerically modeled only to the point where breaking occurs. The depth is

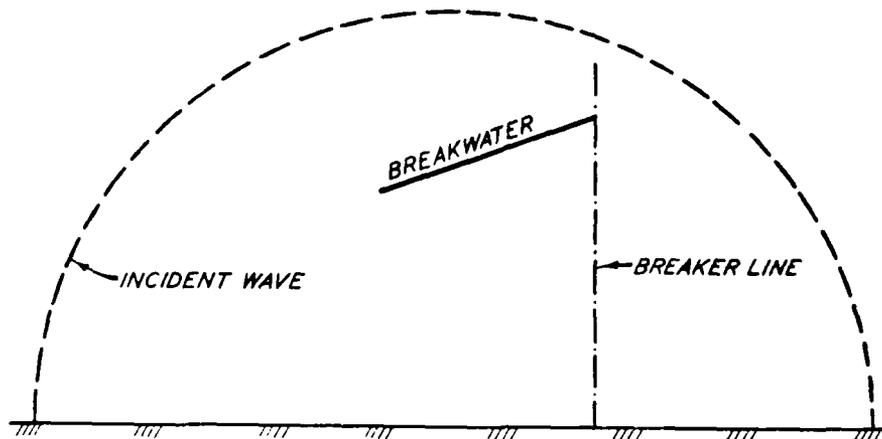

Figure 14. Wave interaction with impermeable breakwater

then increased to the depth of the semi-infinite region surrounding the inner region and the waves are allowed to radiate away from the inner region. Figure 15 shows the finite element grid used for this simulation.

34. Figure 16 shows a typical comparison between the laboratory measurements and the finite element calculations. Also shown is a uniformly valid asymptotic solution derived recently by Liu and Lozano (1979). The solution derived by Liu and Lozano (1979) is in excellent agreement with the laboratory tests. The finite element calculations agree quite well in the shadow zone with the laboratory tests. The agreement is not as good outside the shadow zone. The difference probably is attributable to the artificial increase in depth to allow the waves to radiate from the inner region. This depth transition would cause some energy to reflect back into the inner region.

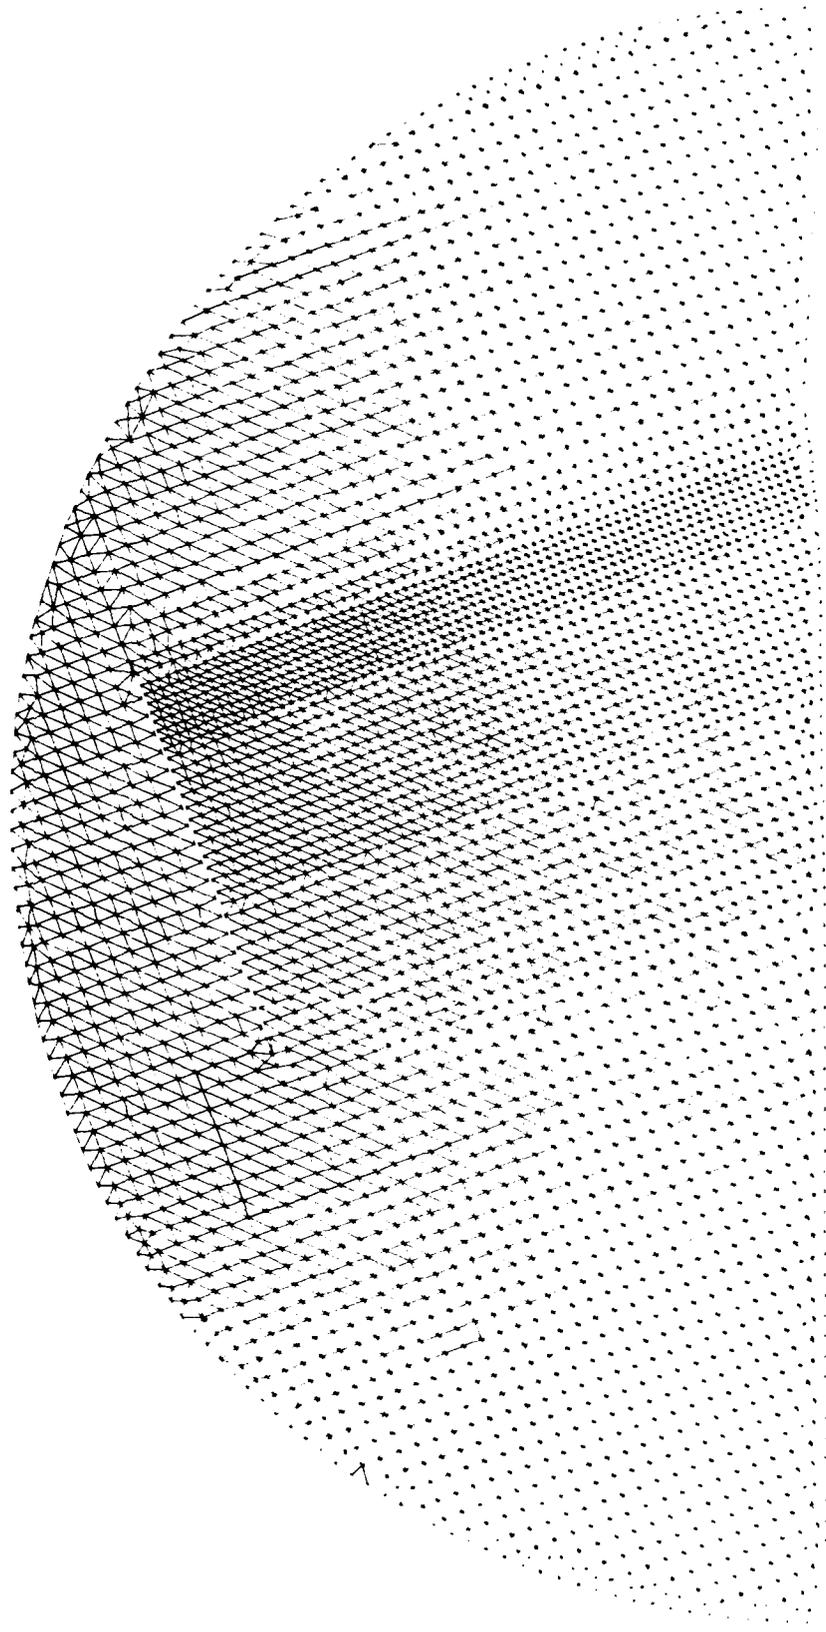

Figure 15. Finite element grid for wave interaction with breakwater

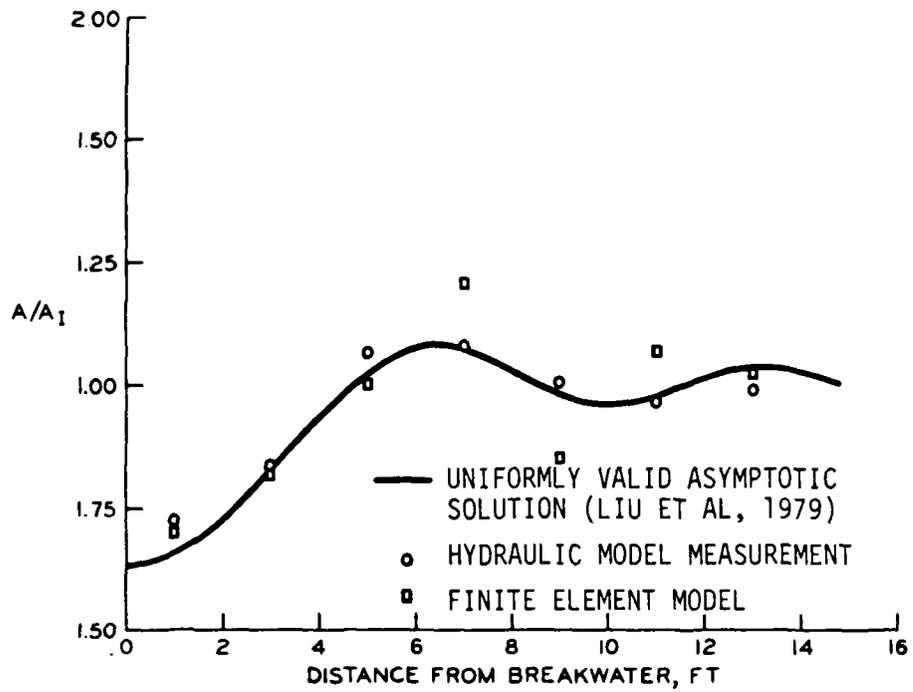

Figure 16. Comparison with laboratory experiments

PART III: INPUT DATA PREPARATION FOR  
FINITE ELEMENT SOLUTION

35. The following example problem is presented to demonstrate the steps and procedures for preparing a finite element grid to be used for the numerical model solution of combined refraction and diffraction. This example outlines the methodology for data manipulation on the computer facilities at the US Army Engineer Waterways Experiment Station (WES).

Data Preparation for Computer Plotting

36. Assume it has been determined that an area of interest such as outlined in Figure 17 is required to be digitized for computer processing of the

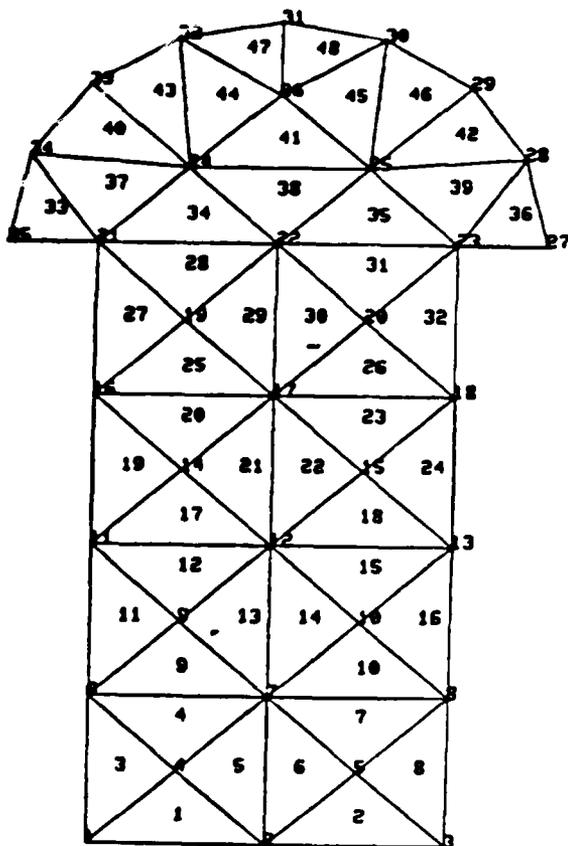

Figure 17. Example problem for demonstrating the preparation of input data for hybrid finite model

hybrid finite element model. The initial determinations after the overall region has been delineated include an orientation so that the elements of the grid can be numbered in continuous fashion. Also, the nodes of the elements should be numbered in a continuous fashion (counterclockwise). The x and y coordinates of each node of the elements are digitized in continuous fashion and recorded for verification later. If the program CONVER is used for converting the measurement of digitized x and y coordinates to prototype units, it is necessary that all x and y values be positive. When the grid has been digitized on magnetic tape, the tape is assigned a number for relocation later.

37. To convert the digitized ASCII tape to BCD tape, run program DIG1 (Figure 18). The steps for performing such an operation include:

```

## Plotting the Finite Element Grid

41. After the finite element grid data have been prepared according to the above procedures, the grid may be plotted by use of the WES Graphics Compatibility System (GCS) (1979) subroutines. The plot file can be directed either to a Calcomp plotter or to a Tektronix 4014 terminal interactively. This program FNGRID listing is presented in Figure 22.

### Steps to run FNGRID

42. Program FNGRID may be run by using the following procedures.
- A. Use the XEDIT mode editor to change the total number of nodal points and elements of the grid.
    - a. Sign on CYBERNET (Control Data Corporation) COMPUTER SYSTEM  
Telephone No. 2047 for 300 Baud  
Telephone No. 2030 for 1200 Baud
    - b. Call out the procedure file PLOTF  
Type in  
GET,PLOTF/UN=CEROMO  
SAVE, PLOTF
    - c. Use XEDIT to make necessary changes  
Type in  
XEDIT
    - d. Type in  
L/IXY/  
The system will respond with  
Q,FNGRID.C/IXY/35/\*;C/NEL/48/\*
    - e. Change the total number of nodes (IXY) and elements (NEL)  
to the desired number  
Type in  
C/35/TOTAL NO. OF NODES/  
C/48/TOTAL NO. OF ELEMENTS/
    - f. Option: If the user does not wish to change data file  
names FINDAT and FINDAT1 to other names, go to  
section g. Otherwise,  
Type in  
C/FINDAT/NEW FILE NAME/  
C/FINDAT1/NEW FILE NAME/
    - g. Type in  
E,,RL  
(This command will terminate the editing mode and the  
file PLOTF will be replaced by the edited version.)

Figure 22. (Sheet 3 of 3)

- B. Use procedure file to run program FNGRID.
- a. Type in  
 OLD,PLOTF  
 BEGIN,RUNPL,PLOTF  
 The system will respond by printing out the statements  
 which are edited by "Q" statement in file PLOTF
  - b. Answer the first question of PROGRAM FILE NAME  
 Type in  
 FNGRID1
  - c. Answer the question of TYPES (X,N,B) OF FILE  
 Type in  
 S
  - d. Answer the question of DEVICE  
 Type in  
 DR4 (if Calcomp plotter is chosen)  
 TK4 (if Tektronix 4014 terminal is chosen)  
 (Note: Computer will begin to plot on the screen if  
 TK4 is chosen; computer will respond with more ques-  
 tions if DR4 is chosen.)
  - e. Answer the question of USER'S ID  
 Type in  
 CEROXX (the user's ID)  
 The system will respond with  
 TAPE 99 ROUTED THRU AJZZ123  
 (where AJZZ123 is the job name of the plot file)
  - f. Call (Ext 3442) the operator of the COPE terminal at the  
 WES Automatic Data Processing (ADP) Center to retrieve the  
 plot file. (Note: TAPE10 is saved and replaced by file  
 name FINDAT after the run, and will be used as data file to  
 run program FINITE.)

Data preparation information

43. The variable names and format allocations for program FNGRID are as follows.

<u>DATA SET NO. 1</u>			
<u>CARD NO. 1</u>			
<u>Col.</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
1 - 5	I5	NDEV	NDEV=0, plot file is directed to the Calcomp plotter NDEV=1, plot file is directed to the Tektronix 4014 terminal
6 - 10	I5	NODR	Number of points on circumference
11 - 15	I5	NCL	NCL=0, full circle grid is used NCL=1, semicircle grid is used

<u>Col.</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
16 - 20	F5.1	FACT	Factor used to change original plot size. (Note: If NDEV=1, then FACT=1.0.)
<u>CARD NO. 2</u>			
1 - 60	10A6	NAME1	Identifier used for the project
<u>CARD NO. 3</u>			
1 - 10	F10.2	SCALE	SCALE=1 and 2, x and y coordinates of the nodes are in feet and inches, respectively
11 - 20	I10	IC1	IC1=0, plot node numbers and element numbers IC1=1, plot element numbers only IC1=2, no number plotted
21 - 30	I10	IC2	IC2=0, no depth data on plot IC2=1, read and plot depth data
<u>CARD NO. 4</u>			
1 - 10	F10.2	XTR	X - coordinate of the center of semicircle
11 - 20	F10.2	YTR	Y - coordinate of the center of semicircle
21 - 30	F10.2	ANGG	Angle of the semicircle (radians)
31 - 40	F10.2	RR	Radius of the semicircle (feet)
<u>CARD NO. 5</u>			
1 - 10	F10.1	WXMAX	The rightmost window boundary (See GCS 1979 manual)
11 - 20	F10.1	WXMIN	The leftmost window boundary (See GCS 1979 manual)
21 - 30	F10.1	WYMAX	The topmost window boundary (See GCS 1979 manual)
31 - 40	F10.1	WYMIN	The bottommost window boundary (See GCS 1979 manual)
<u>CARD NO. 6</u>			
1 - 6	F6.2	XLO	x-coordinate of the lower left corner of the first character of the output (See GCS 1979 manual)
7 - 12	F6.2	YLO	y-coordinate of the lower left corner of the first character of the output (See GCS 1979 manual)

<u>Col.</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
-------------	---------------	----------------------	--------------------

CARD NO. 7

1 - 80	8A10	RTITLE	Title of plot
--------	------	--------	---------------

DATA SET NO. 2

CARD NO. 1

(Note: This data set is obtained after the program CONVER is run.)

1 - 6	Blanks		
7 - 14	F8.3	X(1)	x-coordinate of node 1
15 - 22	F8.3	Y(1)	y-coordinate of node 1
23 - 28	Blanks		
29 - 36	F8.3	X(2)	x-coordinate of node 2
37 - 44	F8.3	Y(2)	y-coordinate of node 2
45 - 50	Blanks		
51 - 58	F8.3	X(3)	x-coordinate of node 3
59 - 66	F8.3	Y(3)	y-coordinate of node 3

(Note: Six values on each card. Total number of x and y values should equal the total number of nodes.)

DATA SET NO. 3

CARD NO. 1

1 - 5	F5.1	DEP(1)	Depth in feet at each nodal point
6 - 10	F5.1	DEP(2)	(Note: Sixteen values on each card, and use as many cards as necessary.)
.			
.			
.			
.			
76 - 80	F5.1	DEP(16)	

DATA SET NO. 4

CARD NO. 1

1 - 5	I5	K(1)	Dummy variable used as an index number for the element
6 - 10	I5	N1(1)	First nodal point of element 1
11 - 15	I5	N2(1)	Second nodal point of element 1
16 - 20	I5	N3(1)	Third nodal point of element 1

Col.	Format	Variable Name	Description
21 - 25	I5	K(2)	Dummy variable
26 - 30	I5	N1(2)	First nodal point of element 2
31 - 35	I5	N2(2)	Second nodal point of element 2
36 - 40	I5	N3(2)	Third nodal point of element 2
41 - 45	I5	E(3)	Dummy variable
46 - 50	I5	N1(3)	First nodal point of element 3
51 - 55	I5	N2(3)	Second nodal point of element 3
56 - 60	I5	N3(3)	Third nodal point of element 3

(Note: Twelve values on each card for as many cards as needed. The order of N1, N2, and N3 of each element is chosen by following a counterclockwise direction.)

#### Example run

44. The finite element grid of Figure 17 will be processed as a typical representative example of the capability of the programs.

- A. Use XEDIT mode to set the total number of nodes to 35 and total number of elements to 48 (Figure 23).

Figure 26c. Listing of data file FD3

The computer plot of the finite element grid originally conceived in Figure 17 is presented in Figure 27 after processing by the programs DIG1, TP2FIL, CONVER, and FNGRID.

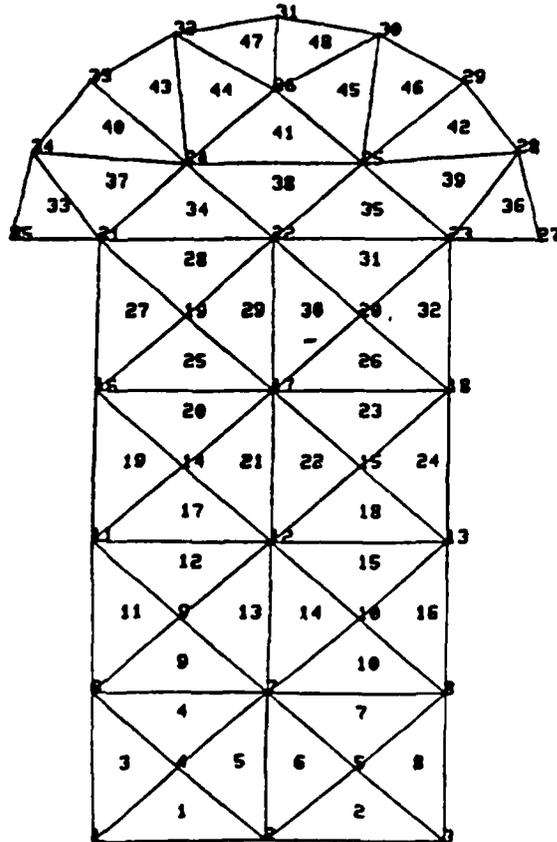

Figure 27. Computer plot of finite element grid

PART IV: PROGRAM FINITE

45. The propagation of periodic, small amplitude surface gravity waves over a variable depth seabed of mild slope is governed by

$$A'' (cc Ad) + \frac{c}{g} l^2 d = 0 \quad (1 \text{ bis})$$

Equation 1 is solved numerically by program FINITE using a hybrid finite element method originally developed by Chen and Mei (1974) to solve the diffraction Helmholtz equation in a constant depth region.

Data Preparation for Program FINITE

46. Two types of data are necessary to run program FINITE: (a) data values defined by parameter statements in the program FINITE and (b) data submitted to the program FINITE by data files. Program FINITE is presented in Figure 28.

Data values defined by parameter statements

47. The following data values are defined by parameter statements in the program FINITE.

<u>Variable Name</u>	<u>Format</u>	<u>Description</u>
NNOD	Integer	Total number of nodes
NELE	Integer	Total number of elements
NODE	Integer	Total number of radiation boundary nodal points
NCS*	Integer	Total number of coefficients in the expansion of radiation domain
ISPT	Integer	Number of selected elevation station (nodes)
ISPTE	Integer	Number of selected elevation station (elements)
NSYSK	Integer	NLGL x NBAND x 2 + 50 (see comment statements in program FINITE)
NSYTP	Integer	NLGL x NBAND + 100 (see comment statements in program FINITE)

(\*Note: The value of NCS is not known a priori. Enough terms must be included such that additional terms have a negligible effect on the solution. NCS can be estimated by determining the argument ( $2\frac{1}{2}R/L$ ) of the J Bessel Functions

(Committee for the Calculation of Mathematical Tables 1958). The values of different order J Bessel Functions with this argument can be determined using Bessel Function tables. When the value of a Bessel Function of higher order becomes much less than the lower order Bessel Function of the same argument, NCS is set equal to the order of the higher order Bessel Function. For  $h = 1$ ,  $k = 12$ ,  $T = 2$  sec;  $l = (\sqrt{gh})T = 11.4$  ft,  $(2\pi R/L) = 6.64$ . Since  $J_{13}(6.64)$  is much less than  $J_0(6.64)$ , NCS is set equal to 13. The model should then be run with NCS equal to both 13 and 14. If the results are the same within desired tolerances, the value of NCS = 13 is confirmed.)

Data values submitted by data files

48. Data file FINDAT1 contains Data Set No. 1 through Data Set No. 3. Data file FINDAT contains Data Set No. 4 through Data Set No. 7. (FINDAT can be obtained after running the plotting program FNGRID.)

DATA SET NO. 1

CARD NO. 1

<u>Col.</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
1 - 80	20A4	ID	This card contains alpha-numeric title that appears in the output for job identification

CARD NO. 2

1 - 5	I5	NBAND	NBAND equals either the maximum difference between two nodes or the sum of NCS and NODR, whichever is greater.
6 - 10	I5	IPR	IPR=1, input data check - echo printed IPR=2, echo not printed
11 - 20	F10.2	RR	Radius of the semicircle (feet)
21 - 30	F10.5	ALPHA	Wave angle of incidence
31 - 40	F10.5	DM	Water depth of the node on the semicircle
41 - 46	I6	IBLKLEN	The value of IBLKLEN should not exceed 31000

CARD NO. 3

1 - 5	I5	IPC	IPC=0, the elevation and velocity at selected elevation stations are omitted IPC=1, the values are printed
6 - 10	I5	IPMAX	IPMAX=0, subroutine CPUNCH will not be called
11 - 15	I5	IDPC	IDPC=0, special procedure for input of average depths for each element is used IDPC=1, read depth at each grid node from cards or from the data files
16 - 20	I5	IDCH	IDCH=1, element number, nodal point, and depth of each element and the x and y coordinates of each node are printed
21 - 25	I5	IBUGA	IBUGA=1, ELK (element stiffness matrix 3 x 3) are printed

<u>Col.</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
26 - 30	I5	IBUGG	IBUGG=1, SYSK(I,1) and SYSK(I,2) are printed
31 - 35	I5	IBUGL	IBUGL=1, SYSO(I) are printed
36 - 40	I5	IDISP	IDISP=1, dispersion included
41 - 45	I5	ICIRC	ICIRC=0, for semicircle grid ICIRC=1, for circular grid
46 - 50	I5	NC	NC=0, selected elevation stations (nodes) will not be punched

CARD NO. 4

1 - 10	F10.2	TMIN	The minimum wave period (seconds)
11 - 20	F10.2	TDELTA	The increment of wave period (seconds)
21 - 25	I5	IKK	The number of times of the increment

DATA SET NO. 2

CARD NO. 1

1 - 5	I5	NSP(1)	Selected elevation station number (nodes), starting from NSP(1) to NSP(ISPT)
6 - 10	I5	NSP(2)	Fourteen values on each card and continuing to the next card as needed
.			
.			
.			
.			
66 - 70	I5	NSP(14)	

DATA SET NO. 3

CARD NO. 1

1 - 5	I5	NSPE(1)	Selected elevation station number (element), starting from NSPE(1) to NSPE(ISPTE)
6 - 10	I5	NSPE(2)	Fourteen values on each card and continuing to the next card as needed

<u>Col.</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
.			
.			
.			
66 - 70	I5	NSPE(14)	
<u>DATA SET NO. 4</u>			
<u>CARD NO. 1</u>			
1 - 10	F10.2	X(1)	x-coordinate at each nodal point, starting from X(1) to X(NNOD)
11 - 20	F10.2	X(2)	Eight values on each card and continuing to the next card as needed
.			
.			
.			
.			
71 - 80	F10.2	X(8)	
<u>DATA SET NO. 5</u>			
<u>CARD NO. 1</u>			
1 - 10	F10.2	Y(1)	y-coordinate at each nodal point, starting from Y(1) to Y(NNOD)
11 - 20	F10.2	Y(2)	Eight values on each card and continuing to the next card as needed
.			
.			
.			
.			
71 - 80	F10.2	Y(8)	

<u>Col.</u>	<u>Format</u>	<u>Variable Name</u>	<u>Description</u>
<u>DATA SET NO. 6</u>			
<u>CARD NO. 1</u>			
1 - 5	Blanks		
6 - 10	I5	NCON(1,1)	Node number of the first nodal point of element 1
11 - 15	I5	NCON(1,2)	Node number of the second nodal point of element 1
16 - 20	I5	NCON(1,3)	Node number of the third nodal point of element 1
21 - 25	Blanks		
26 - 30	I5	NCON(2,1)	Node number of the first nodal point of element 2, etc.
31 - 35	I5	NCON(2,2)	Nine values on each card, starting from NCON(1,1), NCON(1,2), and NCON(1,3) to NCON(NELE,1), NCON(NELE,2), and NCON(NELE,3), respectively, continuing to the next card as needed
.			
.			
.			
.			
56 - 60	I5	NCON(3,3)	

DATA SET NO. 7\*

CARD NO. 1

1 - 10	F10.2	DD(1)	Depth at each nodal point, starting from DD(1) to DD(NNOD)
11 - 20	F10.2	DD(2)	Eight values on each card and continuing to the next card as needed
.			
.			
.			
.			
71 - 80	F10.2	DD(8)	

\*Note: If IDPC=0, Data Set No. 7 is omitted. Depth of each node should be specified by user in the program FINITE.

Procedure to Run Program FINITE

49. To set the correct values for the parameter statements in program FINITE, the following procedure should be followed.

- a. Sign on the Cybernet Computer System  
Telephone No. 2047 for 300 Baud  
Telephone No. 2030 for 1200 Baud
- b. Type in  
GET,FINITE/UN=CEROMO  
SAVE,FINITE
- c. Use XEDIT to set correct values for the parameters in the  
parameter statements  
Type in  
OLD,FINITE  
XEDIT
- d. Locate the first parameter statement  
Type in  
L/PARAMETER/  
The system will respond with  
PARAMETER(NNOD=35,NELE=48,NODR=9,NCS=7,ISPT=35,ISPTE=48)
- e. Change old values in the parameter statement to desired values  
Type in  
C/NNOD=35,NELE=48,NODR=9/NNOD=new value,NELE=new value,NODR=new  
value/  
C/NCS=7,ISPT=35,ISPTE=48/NCS=new value,ISPT=new value,ISPTE=new  
value/
- f. Locate the second parameter statement  
Type in  
N1  
The system will respond with  
PARAMETER(NSYSK=1394,NSYTP=772,NSTMP=84)
- g. Change the values in parameter statement to desired values  
Type in  
C/NSYSK=1394,NSYTP=772/NSYSK=new value,NSYTP=new value/  
C/NSTMP=84/NSTMP=new value/
- h. Replace program file FINITE by edited version  
Type in  
E,,RL

50. Establish an "AFFILE" on the CYBER 205 System. An "AFFILE" enables the Corps of Engineers (KOE) user to transmit files from KOE to the CYBER 205, and vice versa.

- a. Type in  
GET,AFJCL/UN=CEROMO  
SAVE,AFJCL

- b. Use XEDIT to make necessary changes  
Type in  
OLD,AFJCL  
XEDIT
- c. Replace 205USER with actual user's ID of the CYBER 205  
Type in  
C/205USER/USER'S 205 ID/
- d. Replace all PASSWORDS with the actual user's PASSWORD  
Type in  
C/PASSWORD/ACTUAL USER'S PASSWORD/\*
- e. Replace all KOEUSER with actual user's ID of the KOE  
Type in  
T  
This command will bring the pointer to the top of the file  
Type in  
C/KOEUSER/ACTUAL KOE USER'S ID/\*
- f. Replace file AFJCL with the edited version  
Type in  
E,,RL
- g. To execute file AFJCL  
Type in  
GET,ADYJOB/UN=CATHDDC  
BEGIN,,ADYJOB,AFJCL  
The system will respond with

ALL DONE. USER JOB NAME IS COEXXXX

(Note: The status of the job can then be tracked by using "LINK,ENQUIRE." When the job is complete, output will return to the users QGET queue and can be accessed by using the "QLIST" command.)

51. Establish file "QLIST", which enables the KOE users to retrieve CYBER 205 dayfiles and outputs.

- a. Type in  
GET,QLIST/UN=CEROMO  
SAVE,QLIST
- b. Use XEDIT to make necessary changes  
Type in  
OLD,QLIST  
XEDIT
- c. Replace old UID with new UID  
Type in  
C/UID=HASH/UID=XXXX/  
(XXXX is the user's index hash. It can be obtained from "ENQUIRE(B)."  
XXXX are the first four characters of the job name that the system  
assigned to the user.)
- d. Replace KOEUSER with user's ID  
Type in  
C/KOEUSER/USER'S ID/

- e. Replace old header with user's header  
Type in  
C/HEADER1/USER'S HEADER/  
C/HEADER2/USER'S HEADER/  
C/HEADER3/USER'S HEADER/
  - f. Replace file QLIST with the edited version  
Type in  
E,,RL
52. Create an Update Library
- a. Type in  
GET,FINUP1/UN=CEROMO  
BEGIN,RUNF,FINUP1  
The system will respond with  
15.56.20 SUBMIT COMPLETE. JOB NAME IS AJZZXXX
  - b. Check dayfile  
Type in  
OLD,DAY1  
LIST
53. Establish an Update Correction File
- a. Type in  
GET,FINDIR/UN=CEROMO  
SAVE,FINDIR
  - b. Use XEDIT to make necessary changes and replace the file FINDIR with the edited version
54. Run program FINITE with Update Correction File FINDIR (Figure 29).
- a. Type in  
GET,FINI/UN=CEROMO  
SAVE,FINI
  - b. Use XEDIT to make necessary changes  
Type in  
OLD,FINI  
XEDIT
  - c. Replace 205USER with the CYBER 205 user's ID  
Type in  
C/205USER/CYBER 205 USER'S ID/
  - d. Replace PASSWORD with user's PASSWORD  
Type in  
C/PASSWORD/USER'S PASSWORD/
  - e. Replace all KOEUSER with user's KOE USER ID  
Type in  
C/KOEUSER/USER'S KOE USER ID/\*
  - f. Change data file name (optional)\*  
Type in  
C/FINDAT1/NEW FILE NAME/  
C/FINDAT/NEW FILE NAME/

(\*See Note, page 83)

(\*Note: File FINDAT1 contains Data Set No. 1 through Data Set No. 3. File FINDAT contains Data Set No. 4 through Data Set No. 7. File FINDAT can be obtained at the completion of the run of the plotting program FNGRID. If that is the case, the new file name replacing FINDAT should correspond with the file name that was used to save TAPE10 in the procedure file PLOTF.)

- g. Replace file FINI with the edited version  
Type in  
E,,RL
- h. To execute file FINI  
Type in  
SUBMIT,FINI
- i. To check job status  
Type in  
LINK,ENQUIRE,PD=MODD,PT=HHMM  
(PD=MODD, where MO is the month from 01 to 12, and DD is the date from 01 to 31. PT=HHMM, where HH is the hour from 01 to 24, and MM is the minute from 01 to 60. Example: To generate status information for a job received since 9:00 a.m. on 31 May, type in  
LINK,ENQUIRE,PD=0531,PT=0900  
The last three characters of the run JOB NAME will not stay the same as in initiated job names. The system assigns different names at different stages that transmit a job from KOE to CYBER 205, or vice versa. If the job output is available at KOE, then continue to the next step.)
- j. To execute "QLIST"  
Type in  
OLD,QLIST  
BEGIN,,QLIST,XXX,LSV,DSV  
(where XXX are the last three characters of the job name that appeared in the statement "JOB NAME IS IN USER QGET QUEUE."  
LSV causes the output to be saved with file name HASHXXX.  
DSV causes the dayfile to be saved with file name DAYXXX.)
- k. To list output and dayfile on the user's terminal  
Type in  
OLD,FILE NAME  
LIST
- l. To direct output and dayfile to a fast printer at COPE terminal  
Type in  
GET,LFN=FILE NAME  
ROUTE,LFN,DC=PR,UN=COPE USER'S ID  
(where LFN is the local file name, and FILE NAME is the permanent file name)

#### A Sample Application

55. In this sample application to demonstrate the execution of program

FINITE on the CYBER 205 COMPUTER SYSTEM, the values of the parameters in the parameter statements stay unchanged.

- a. Obtain the source file FINITE  
Type in  
GET,FINITE/UN=CEROMO  
/SAVE,FINITE
- b. Establish AFFILE "AF205" on CYBER 205
  1. To execute file AFJCL

```

GET,AFJCL/UN=CEROMO
/SAVE,AFJCL
/OLD,AFJCL
/XEDIT
XEDIT 3.1.00
?? C/205USER/052010/
USER(U=052010,PA-PASSWORD)
?? C/PASSWORD/IODINE/*
USER(U=052010,PA-IODINE)
--EOR--
USER(KOEUSER,IODINE,KOE)
END OF FILE
?? T
?? C/KOEUSER/CEROMB/*
CHARGE(CEROEGC,CEROMB)
--EOR--
USER(CEROMB,IODINE,KOE)
CHARGE(CEROEGC,CEROMB)
END OF FILE
?? E,RL
AFJCL   REPLACED
AFJCL   IS A LOCAL FILE
AEB ,   0.257UNTS.
/GET,ADYJOB/UN=CATHOIC
/BEGIN,,ADYJOB,AFJCL
ALL DONE.  USER JOB NAME IS COE429
$REVERT.
/

```

2. Use "LINK,ENQUIRE" to check job status

```

LINK,ENQUIRE,JN=COE429
STATUS FOR CEROMB /KOE

```

DATE	TIME	USER	SYSTEM	FILE	FILE
MMDD	HHMM	JOB NAME	JOB NAME	TYPE	STATUS

## PART V: SUMMARY

56. A two-dimensional finite element numerical simulation model (FINITE) was developed that calculates wave heights under combined refraction and diffraction of both long and short waves approaching structures from any arbitrary direction. The wave equation solved governs the propagation of periodic, small amplitude surface gravity waves over a variable depth seabed of mild slope. The efficient formulation of the model permits the solution of large problems with relatively small time and memory storage requirements. A computational scheme is employed that allows the solution of practical problems that typically require large computational grids.

57. Although the model solves an equation that is strictly valid only for mild bathymetric variations, the model can provide reasonable answers for problems where there are rapid depth variations (at much lower cost than required by three-dimensional models that are appropriate for problems involving rapid depth variations). Comparisons are presented between the finite element model calculations and an analytical solution, a two-dimensional numerical solution, a three-dimensional numerical solution, and measurements from laboratory studies. Because the finite element FINITE does not provide a mechanism for energy dissipation, energy loss through wave breaking can be simulated only by permitting waves to propagate out of the computational region. The program documentation, user guide, and sample problem output are provided.

## APPENDIX A: NOTATION

a	Wave amplitude, ft
A	Numerical computational region, dimensionless
A	Wave amplitude, ft
$A_I$	Incident wave amplitude, ft
B	Numerical computational region, dimensionless
c	Wave phase velocity $(g/k \tanh kh)^{1/2}$ , ft/sec
$c_g$	Wave group velocity $(1/2c(1 + G))$ , ft/sec
$F(\phi)$	Mathematical functional, dimensionless
g	Gravitational constant, 32.174, ft/sec <sup>2</sup>
G	Computational parameter $(2 k h / \sinh 2 kh)$ , ft/sec
h	Still-water depth, ft
$H_n$	Hankel function of the first kind, dimensionless
i	$(-1)^{1/2}$ , dimensionless
k	Wave number, $2\pi/L$ , 1/ft
$k_o$	Incident wave number, $2\pi/L_o$ , ft
K	Symmetric complex coefficient matrix, dimensionless
L	Arbitrary wavelength, ft
$L_o$	Incident wavelength, ft
n	Unit normal, dimensionless
$n_A$	Unit normal to the boundary separating computational regions A and B, dimensionless
N	Number of node points in the finite element discretization, dimensionless
r	Radial variables, ft
T	Wave period, sec
$\bar{u}$	Two-dimensional velocity vector, ft/sec
$\alpha_n$	Constant coefficients in Hankel functions, dimensionless
$\beta_n$	Constant coefficients in Hankel functions, dimensionless
$\theta$	Angular variable in polar coordinates, deg
$\phi$	Velocity potential defined by $\bar{u} = \nabla\phi$ , ft <sup>2</sup> /sec
$\phi_A$	Velocity potential in region A, ft <sup>2</sup> /sec
$\phi_B$	Velocity potential in region B, ft <sup>2</sup> /sec
$\phi_I$	Incident wave velocity potential, ft <sup>2</sup> /sec
$\phi_R$	Reflected wave velocity potential, ft <sup>2</sup> /sec

- $\omega$  Angular frequency,  $2\pi/T$ , 1/sec  
 $\nabla$  Horizontal gradient operator, dimensionless
